Interaction of Monetary and Fiscal Policies through the lens of a semi-structural model: the case for Central America and the Dominican Republic
Introduction

In the Dominican Republic, as well as other economies from Central America, the Central Bank follows an inflation target strategy, where the interest rate is the policy instrument.

In this sense, the CB uses its policy interest rate to influence the market rates relevant for the consumption and investment decisions of agents in the economy.

We study the link between fiscal and monetary policy, highlighting the interest rate channel of fiscal shocks.

If this is important then the monetary policy transmission mechanism is going to be affected by active fiscal policy.
The fiscal policy on structural and semi-structural models

Botman et al (2006): A NKM where the structure imposed in the model allows for non-Ricardian individuals, hence capturing the effects of the fiscal policy on different macroeconomic variables.

Fiscal and monetary policy

Canova & Pappa (2011): Empirical study analyzing the conditions in which the fiscal multiplier is greater than 1, including the case where the monetary policy is accommodative.

Dupport & Li (2014): Testing the hypothesis that an increase in government spending will increase GDP if the central bank does not react strongly to inflation.

Dai & Phillippon (2005): They study the relationship between the fiscal policy and the term structure of market interest rates.

Bredemeier et al (2015): In a traditional structural model, they introduce a spread between the monetary policy rate and the market relevant rate, finding that this spread reacts to government spending.
The spread between policy and market rate is not constant overtime

Empirical strategy

The interaction between monetary and fiscal policy is evaluated through the lens of a semi-structural model for a small open economy.

The transmission mechanism emphasizes the link between market interest rates and public spending. Therefore, in this model there are two mechanism through which fiscal policy affect the economy and interacts with monetary policy:

1) A “direct” channel through which fiscal shocks affects aggregate demand, pushing interest rates up, as central bank stabilizes output gap and inflation.

2) An “indirect” channel through which the higher spending is financed using domestic credit, rising interest rate and crowding out the effects of expansive monetary policy.

Despite we specify both channels in the model, we have interest in the estimation of the parameters that characterizes the sensitivity of market rates to fiscal shocks.
Determination of market interest rates:

\[ i_t^m = i_t^{tpm} + \phi_t \]

\[ \phi_t = \phi_g(fiscal_t) + X\beta + \epsilon_t^\phi \]

\[ i_t^{tpm} = \theta_i i_{t-1}^{tpm} + (1 - \theta_i)(\bar{r} + \theta_\pi(E_t\pi_{t+1} - \bar{\pi}) + \theta_\gamma \hat{y}_t) + \eta_t^{tpm} \]

\[ r_t = i_t^m - E_t\pi_{t+1} \]

\[ \hat{r}_t = r_t - \bar{r} \]

where:

- \( i_t^m \): market interest rate (commercial banks)
- \( i_t^{tpm} \): monetary policy rate
- \( \phi_t \): spread
- \( fiscal_t \): public spending, domestic debt or fiscal deficit
- \( X \): macro and financial controls
- \( \bar{r} \): long-run equilibrium interest rate
- \( \eta_t^{tpm} \)

Note: \( \overline{var}_t = var_t - var_{ss} \)
Determination of market interest rates:

We consider 2 specifications for $\phi(\hat{g}_t)$:

1) Lineal (one regime)

$$\phi(\hat{g}_t) = \phi \hat{g}_t$$

2) Markov switching (two regimes)

$$\phi(\hat{g}_t) = \begin{cases} \phi_1 \hat{g}_t & \text{if } S_t = 1 \\ \phi_2 \hat{g}_t & \text{if } S_t = 2 \end{cases}$$

and the transition matrix:

$$\Pi = \begin{bmatrix} p_{11} & 1 - p_{11} \\ 1 - p_{22} & p_{22} \end{bmatrix}$$

with $P[S_t = j | S_{t-1} = i] = p_{ij}$, for $i, j = 1, 2$. 
Rest of the model

Aggregate demand

\[ \hat{y}_t = \beta_1 \hat{y}_{t-1} + \beta_2 E_t \hat{y}_{t+1} - \beta_3 \hat{r}_t + \beta_4 \hat{z}_t + \beta_5 \hat{y}^*_t + \beta_6 \hat{g}_t + \eta_t \hat{\gamma} \]

where:

\( \hat{y} \): output gap
\( \hat{r} \): real interest rate gap
\( \hat{z} \): real exchange rate gap
\( \hat{y}^* \): foreign demand gap
\( \hat{g} \): public spending gap
\( \eta \hat{\gamma} \): demand shock
Rest of the model

Phillips curve:

\[ \pi_t = \alpha_1 \pi_{t-1} + \alpha_2 E_t \pi_{t+1} + \alpha_3 \hat{y}_t + \alpha_4 \hat{z}_t + \eta^\pi_t \]

where:

\( \pi_t \): CPI inflation

\( \hat{y} \): output gap

\( \hat{z} \): real exchange rate gap

\( \eta^\pi \): cost-push shock
Rest of the model: Fiscal policy

\[ \hat{g}_t = \beta^g_1 \hat{g}_{t-1} + \varepsilon^g_t \]
\[ \hat{t}_t = \beta^t_1 \hat{t}_{t-1} + (1 - \beta^t_1)(\overline{d^T_t}) + \varepsilon^{tt}_t \]
\[ \hat{b}_t = \frac{g_{ss}}{b_{ss}} \hat{g}_t - \frac{t_{ss}}{b_{ss}} \hat{t}_t \]
\[ \hat{d}_t = \left( \frac{1+r_{ss}}{1+g^y_{ss}} \right) \left( \hat{d}_{t-1} + \hat{i}^{TPM}_t - \hat{g}_t^y - \hat{\pi}_t \right) + \left( \frac{g^y_{ss} + r_{ss}}{1+g^y_{ss}} \right) \hat{b}_t \]
\[ \hat{d}^*_t = \left( \frac{(1+r^*_ss)+(1+\rho_{ss})+(1+\Delta z_{ss})}{1+g^y_{ss}} \right) \left( \hat{d}^*_{t-1} + \hat{i}^*_t + \Delta s_t + \rho_t - \hat{g}_t^y - \hat{\pi}_t \right) + \left( 1 - \frac{(1+r^*_ss)+(1+\rho_{ss})+(1+\Delta z_{ss})}{1+g^y_{ss}} \right) \hat{b}_t \]
\[ \overline{d^T}_t = \emptyset \hat{d}_t + (1-\emptyset) \hat{d}^*_t \]

Where: \( \hat{d}_t, \hat{d}^*_t \) and \( \overline{d^T}_t \) represent domestic debt, external debt and total debt;
\( \hat{g}_t, \hat{t}_t \) and \( \hat{b}_t \) represent public expenditure, tax rate and primary government balance.
Rest of the model

UIP condition:

\[ i^m_t = i^*_t + \Delta E_t S_{t+1} + \rho_t + \eta^i_t \]

Risk premium:

\[ \rho_t = (1 - \theta_\rho) \bar{\rho} + \theta_\rho \rho_{t-1} + \eta^\rho_t \]

Real exchange rate:

\[ z_t = s_t + p^*_t - p_t \]

Real exchange rate gap:

\[ \hat{z}_t = z_t - \bar{z} \]

Foreign inflation:

\[ \pi^*_t = (1 - \phi_{\pi^*}) \bar{\pi}^* + \phi_{\pi^*} \pi^*_t + \eta^\pi_t \]

Foreign interest rate:

\[ i^*_t = (1 - \phi_{i^*}) \bar{i}^* + \phi_{i^*} i^*_t + \eta^i_t \]
Estimation

• Model is estimated using bayesian methods for the Dominican Republic, Costa Rica and Guatemala.

• Different fiscal indicators are considered in the equation for interest rate spread.

• Observable variables included are: GDP, CPI, NER, MPR, commercial bank interest rate, primary deficit, public domestic debt, public expenditure and and commercial banks’ non performing loans and solvency ratio.

• Observable foreign variables considered in the estimation are: CPI, GDP, interest rate and EMBI.
Estimation results: Dominican Republic

Country: Dominican Republic
Dependent variable: Interest rate spread

(With interaction)
Concluding remarks and next steps

• The interaction between fiscal and monetary policy is key to understanding the transmission mechanism of the policy taken.

• Our estimation’s show that fiscal variables play a role in determining the market interest rates in the selected countries, hence affecting the transmission mechanism of monetary policy.

• Our next step is to verify if this relationship is constant over different fiscal fiscal regimes.
Interaction of Monetary and Fiscal Policies through the lens of a semi–structural model: the case for Central America and the Dominican Republic
